Abstract—This report addresses the problem of classifying grayscale document images into 16 different categories. The objective is to replicate the original DocFormer [1] and LayoutLM [2] models, achieve a minimum accuracy threshold of 75%, and implement the solution as a cloud service using Docker. The report presents an analysis of the RVL-CDIP dataset [3], explores pre-processing techniques, and discusses different deep learning architectures such as CNNs and transformers. The performance of various models, including GoogleNet, ResNet50, VGG16, and DocFormer, is evaluated using metrics such as accuracy, precision, recall, and F1-score. The results show that combining visual information and textual content improves accuracy compared to CNN architectures alone. The report concludes with insights, limitations, and lessons learned during the project.

1. Introduction

Document image classification is an important task in the field of computer vision and natural language processing. The ability to automatically categorize and classify documents has numerous practical applications, ranging from information retrieval and document organization to automated data extraction and content analysis. In this report, we address the problem of classifying grayscale document images into 16 distinct classes or document types.

The task at hand involves developing a model that can accurately classify document images based on their visual content. The training dataset consists of a large number of grayscale document images, each belonging to one of the 16 predefined classes. Our objective is to replicate the performance of the original DocFormer and LayoutLM models, which have shown promising results in document understanding and classification.

To achieve this, we will explore various deep learning architectures, including convolutional neural networks (CNNs) and transformer-based models. We will leverage the RVL-CDIP dataset, which provides a diverse range of document images characterized by low quality, noise, and low resolution. The dataset poses challenges due to its large size and class imbalance, requiring careful consideration in model development and evaluation.

The ultimate goal of this project is to develop a robust document image classification system with a minimum accuracy threshold of 75%. Furthermore, we aim to deploy the solution as a cloud service using Docker, making it easily accessible and scalable for real-life implementation. To assess the performance of our models, we will evaluate key metrics such as accuracy, precision, recall, F1-score, and analyze the confusion matrix and ROC AUC curve.

Through this project, we seek to gain insights into the effectiveness of different deep learning architectures for document image classification. Additionally, we aim to explore the benefits of incorporating optical character recognition (OCR) technology to extract text from document images and enhance classification accuracy.

1.1. Problem Statement

Given a set of grayscale document images, the task is to classify each image into one of the 16 classes or document types. The training dataset consists of 48000 images with 3000 images belonging to each class. Example images are provided below for some classes. The dataset was collected from the RVL-CDIP dataset.

1.2. Objectives

- Replicate the original DocFormer and LayoutLM models
- Achieve an accuracy threshold of atleast 75%
- Real life implementation and deployment into a cloud service using Docker

1.3. Metrics

- Accuracy
- Precision
- Recall
- F1-score
- Confusion Matrix
- ROC AUC

1.4. Meta-data

The RVL-CDIPdataset consists of scanned document images belonging to 16 classes such as letter, form, email, resume, memo, etc. The dataset has 320,000 training, 40,000 validation and 40,000 test images. The images are characterized by low quality, noise, and low resolution, typically 100 dpi. The data used for this problem statement is based on the above mentioned dataset. The dataset at hand has document images, categorized into train and test directories. These directories contain image (.tiff) files. There is also a file for labels which has id and it's corresponding label for mapping.

The dataset contains 16 classes of documents, which are:

- memo
- form
- email
- handwritten
- advertisement
- scientific report
- scientific publication
- specification
- file folder
- news article
- budget

2. Exploratory Ananlysis

The dataset is clean as it's been provided on kaggle. There isn't much analysis apart from the images themselves. [4]

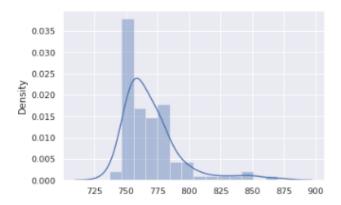

Figure 1. Distribution Plot of the Data

The above distplot provides the class distributions for the different classes. There is a class imbalance which can have an impact on the performance of the classifier. While outputting the different images from each class shows that some classes like files and folder doesn't have that well defined images, the reason could be the way the images were processed.

3. Preprocessing Pipeline

For the baseline model, we are using CNN models. So for that we will be using the required tasks like applying convolutinal kernels for extracting feature map, and experiment with it and the pooling operations. Further we will be moving along with experimentations with different models like transformer networks and OCRs.

3.1. Approach

The topic of document page image classification has received much publicity over the last few years. In fact the RVL-CDIP dataset was curated specifically to test image classification strategies on document images. Earlier studies focused heavily on the original AlexNet [5] architecture. More recently modern architectures such as VGG16 [6], GoogleNet5 [7], and ResNet50 [8] have been proposed and tested on RVL-CDIP. The current state-of the-art utilizes a set of 5 distinct VGG16 models, one for the whole image (known as the holistic model, initialized with pre-trained ImageNet weights) and 4 for specific subsections of the image (header, footer, left body, and right body initialized on the holistic trained weights) [9]. These 5 models are then combined to form a final prediction. While accurate, the number of parameters is immense (on the order of 10⁸) and the training process is sequential, requiring a holistic model to be trained before any of the subsection models can be trained. In addition to the aforementioned image classification strategies, we can take advantage of optical character recognition (OCR) technology to extract text from document page images and train text classification algorithms. Many approaches have been developed to deal with text classification problems [4], although most have been developed under the assumption of clean encoded text. There is evidence to support that the bag-of words approach is quite robust to the unavoidable transcription errors. In this project we explore combining both approaches into a single classification task, i.e. we construct a model that uses both the visual information and the textual content of page to make a decision. We also explore the possibilities of including LayoutLM model for POS embedding and drawing bounded boxes to extract special features using NLP, as well as a multi-modal Architecture based on VGG16 and exploring the results.

4. Baseline Transfer Learning CNN Models

4.1. Hyperparameters

We empirically determined good training schemes for each dataset. For RVL-CDIP, CNNsare trained with Stochastic Gradient Descent (SGD) with mini-batches of 32 for 500,000 weight updates. The initial learning rate (LR) is 0.001 and is decayed by a factor of 10 every 150,000 minibatches. We also use Momentum optimizer with Beta set to 0.9.All networks are trained on the training split

and progress is monitored on the validation set. The set of network parameters that performed best on the validation set is then evaluated on the test images. In this work, we use test set accuracy as our evaluation metric. CNNs require days to train on high-end GPUs, so training many CNNs for statistical significance testing is often too time-consuming. For this reason, CNN literature almost always reports numbers from only a best single trained model. Thus, we typically report average performance of 1-2 CNNs.

4.2. Input Shape

Standard CNN architectures accept inputs that are 224x224, but to our knowledge, this design. choice has not been thoroughly explored before. At this resolution, large text is generally legible, but smaller text is not. We empirically test square input sizes $n \times n \mid n = 32, 64, 100, 150, 227, 256, 320, 384, 512.$

Of necessity, we modify the architecture of the CNN for each input size with the following principles.

- Same number of layers
- Increase kernel size and network width with input size
- Spatial output size of final convolution layer is 6x6

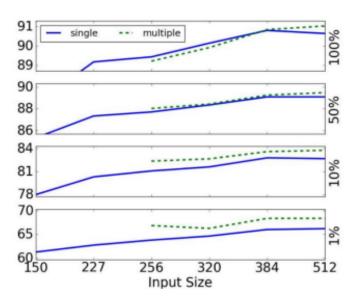

Figure 2. Accuracy vs Input Size

Solid blue lines are for CNNs trained with a single input size. Dashed green lines are for CNNs trained with variable sized input images. The x-axis location corresponds to the largest input size used to train the CNN. For example, the performance of the CNNs trained with images of size 256-384 is plotted at x = 384. An exhaustive grid search over possible architectures was not possible with our computational resources. All models have been evaluated based on the accuracy of the output and Loss.

4.3. Tested Architectures

4.3.1. GoogleNet. Over 20 epochs,

Training accuracy: 47.57%, Validation accuracy: 51.07%

Figure 3. GoogleNet - Loss vs Epochs

4.3.2. ResNet50. Over 60 epochs,

Training accuracy: 61.23%, Validation accuracy: 58.25%

Figure 4. ResNet50 - Loss vs Epochs

4.3.3. VGG16. Over 60 epochs,

Training accuracy: 49.59%, val accuracy: 61.20%

Figure 5. VGG16 - Loss vs Epochs

4.3.4. Result. While CNN architectures by themselves give a decent performance, it is nothing to write home about. Incorporating the extracted text from the documents using OCR however, should give us a better result. This may give the models an insight into the actual content of the documents and in theory should yield better accuracy and lower loss.

5. DocFormer: Multi-Modal Approach

5.1. Model Architecture

DocFormer is an encoder-only transformer architecture. It also has a CNN backbone for visual feature extraction. All components are trained end-to-end. DocFormer enforces deep multi-modal interaction in transformer layers using novel multi-modal self-attention. We describe how three modality features (visual, language and spatial) are prepared before feeding them into transformer layers.

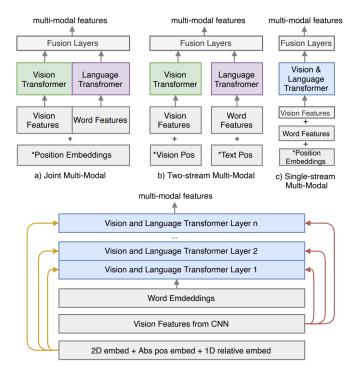

Figure 6. DocFormer Architecture

5.2. Visual Features

Let $v \in \mathbb{R}^{3 \times h \times w}$ be the image of a document, which we feed through a ResNet50 convolutional neural network $f_{cnn}(\theta,v)$. We extract lower-resolution visual embedding at layer 4, i.e $v_{l_4} \in \mathbb{R}^{c \times h_l \times w_l}$. Typical values at this stage are c=2048 and $h_l=\frac{h}{32}$, $w_l=\frac{w}{32}$ (c = number of channels and h_l and w_l are the height and width of the features). The transformer encoder expects a flattened sequence as input of d dimension. So we first apply a 1×1 convolution to

reduce the channels c to d. We then flatten the ResNet features to $(d, h_l \times w_l)$ and use a linear transformation layer to further convert it to (d, N) where d = 768, N = 512. Therefore, we represent the visual embedding as $\overline{V} = linear(conv_{1\times 1}(f_{cnn}(\theta, v)))$.

5.3. Language Features

Let t be the text extracted via OCR from a document image. In order to generate language embeddings, we first tokenize text t using a word-piece tokenizer to get ttok, this is then fed through a trainable embedding layer Wt. t_{tok} looks like $[CLS], t_{tok1}, t_{tok2}, ..., t_{tokn}$ where n=511. If the number of tokens in a page is >511, we ignore the rest. For a document with fewer than 511 tokens, we pad the sequence with a special [PAD] token and we ignore the [PAD] tokens during self-attention computation. We ensure that the text embedding, $\overline{T} = W_t(t_{tok})$, is of the same shape as the visual embedding \overline{V} . Following, we initialize W_t with LayoutLMv1 pre-trained weights.

5.4. Spatial Features

For each word k in the text, we also get bounding box coordinates $b_k = (x_1, y_1, x_2, y_2, x_3, y_3, x_4, y_4)$. 2D spatial coordinates b_k provide additional context to the model about the location of a word in relation to the entire document. This helps the model make better sense of the content. For each word, we encode the top-left and bottom-right coordinates using separate layers W^x and W^y for x and y-coordinates respectively. We also encode more spatial features: bounding box height h, width w, the Euclidean distance from each corner of a bounding box to the corresponding corner in the bounding box to its right and the distance between centroids of the bounding boxes.

5.5. Multi-Modal Self-Attention Layer

We now describe in detail the novel multi-modal self-attention layer. Consider a transformer encoder $f_{enc}(\eta,\overline{V},\overline{V_s},\overline{T},\overline{T_s})$, where η are trainable parameters of the transformer, $\overline{V},\overline{V_s},\overline{T},\overline{T_s}$ are visual, visual-spatial, language and language spatial features respectively, and are obtained as described previously. Transformer f_{enc} outputs a multi-modal feature representation \overline{M} of the same shape d=768, N=512 as each of the input features. Self-attention, i.e., scaled dot-product attention, for a single head is defined as querying a dictionary with key-value pairs.

5.6. Document Classification Task with DocFormer

For this task we use pooled features to predict a classification label for a document. The RVL-CDIP dataset consists of 400,000 grayscale images in 16 classes, with 25,000 images per class. However due to resource limitations, we were only able to train the model with a smaller subset of the dataset. Overall there are 9,000 training images, 3,000

validation images. We report performance on test and eval metric is the overall classification accuracy. In line with prior text and layout information is extracted using Textract OCR.

6. Observations

The following table shows the various observations of expirements with the aforementioned models.

TABLE 1. OBSERVATIONS

Model	Train Accuracy	Val Accuracy	Precision	Recall
DocFormer	68.20 %	70.70 %	0.707	0.707
LayoutLM	58.95 %	57.40 %	0.573	0.573
CNNs	59.50 %	60.50 %	0.604	0.604

6.1. ROC AUC Curve

The ROC AUC Curve obtained as follows:

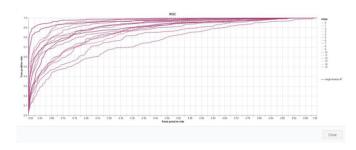

Figure 7. ROC AUC Curve

6.2. Confusion Matrix

The confusion matrix for the dataset is as follows:

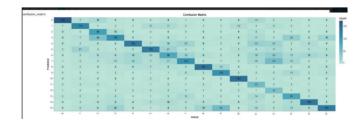

Figure 8. Confusion Matrix

6.3. CNN vs Transformers

As we've experienced throughout the course of this project that our task of Document classification can be done easily using a CNN based network approach. However, going with a transformer network helps us capture the visual NLP part which does provide us with a better classifier. The accuracies tabulated above shouldn't be the only thing we [6] K. Simonyan and A. Zisserman, "Very deep convolutional networks for consider while building our classifier.

7. Conclusion

Towards the end of the project, we have spent a fair amount working with different types of CNN architectures. Different forms of information extracting through OCRs for Visual NLP as the it enhances the performance and applicability of our classifier. Through this project we've learnt a variety of new things one of which was working with pyTorch since the later transformer models weren't in the tensorflow framework which we have used in the labs.

Overall, we can achieve an accuracy in the neighbourhood of 60% which is less than what we targeted while starting this project. One integral part of learning has been learning that literature review is also an integral part of any project as it gives us insights and a-priori knowledge before going ahead with the project. Another hurdle in our way was that the research work conducted for the same task was with a dataset which wasn't easily available and easy to work with because of its sheer size making it even harder to replicate the results from the different research papers. This adds to our skillset yet another useful and valuable skill, from report writing to literature review to pipelining all the way up-to deployment.

We had placed our bets on the DocFormer model to give us a good training accuracy, which it did, which again proves that having done good literature review goes a long way. Another point to add here is that the task domain is still very much in research with the latest findings being published on 22nd October 2022, which was the working timeline of this project so being able to take such a task and make a useful working product out of it does make a valuable experience for us. All in all, moving past those hurdles we were able to successfully accomplish our goals.
